Aircraft Stress | Guide to aerospace structure analysis

Aircraft structural members are designed to carry a load or to resist stress. Every part of the aircraft must be planned to carry the load to be imposed upon it. The determination of such loads is called stress analysis. The term "stress" is often used interchangeably with the word "strain." The degree of deformation of a material is strain.

Torsion is produced in an engine crankshaft while the engine is running. Forces that produce torsional stress also produce torque. All structural members of an aircraft are subject to one or more stresses. Sometimes a structural member has alternate stresses; for example, it is under compression one instant and under tension the next.
